PROJECT ORION

People may experience some issues while providing a connection to the internet wirelessly in their houses which have concrete shear walls especially. Signal power attenuation is due to the range and more by the solid objects while the signals are passing through them.

There are several wireless network systems to get over this issue. Most common solution is mesh systems for that, but these systems would cost too much (approx. \$180.00) to the home residents and SMEs. Therefore, many people are trying to solve it by setting up access points to the different places that signals cannot reach from the origin wireless point. Although it is not a solution literally. There is an option in access points' interface which is called "roaming". The option enables an auto connection to the nearest wireless point seamlessly but only when the connection has been lost to the current wireless point. It's mean that the option cannot supply an auto-switch to the wireless point which has the strongest signal that device's get. You have to select a wireless point that you want to connect or switch off your device's Wi-Fi and switch it on again to connect to the strongest wireless point.

At this point our software moves in to handle all the issues which have been mentioned above. It has the ability to switch to the strongest signal that device's get without needing manual intervention. Our team is planning to get over this problem by using Wi-Fi list, sensor and GPS data efficiently as much as possible with less battery consumption. Our software will be running in the background by measuring the strongest signal periodically to reduce the battery consumption. We will add an option into it to determine how many seconds this period will be. The software is designed for the android devices at first because it is the most needed and open source platform. This is an advantage for our team. In the future, we are planning to expand it to the other platforms like Windows, Linux.
